

Trying to go past the number line? Here's how to start circle math. I'll help you out of the cave.

Step A: Make a circle.

Define that as infinity or 0, I do not care.

0

Step B: Start from one point on it, draw inside it a smaller circle. That circumference equals neutral one.

$\overline{(0)}$

Step C: As you start from that connection point up to one, you get fractions in a sense and as you pass one you go to infinity, aka big. Here the famous: 0, 1, and infinity representing that connective point.

Step D: Draw another circle on the other side. They'll connect in the center of the biggest circle. That creates the two infinities and two charges.

$-(\infty)+$

Step E: The interior of the charged circles are i and $-i$, while the circumference are the positive and negative numbers you all fawn over. One side of the negative circle goes to $-\infty$ the other side going to -0 . The other positive circle is the opposite with going to $+\infty$ the other side going to $+0$.

Step F: Rotate the bigger circle and like a pulley or gear, they move in unison. Let there be light or time or whatever phrasing work.

Step G: Put three circles inside one. Equally size they cannot turn in unison so one is smaller with a more erratic spin to the other two $\pm$ -circles. It can have 0, 1, or 2 connection points

Step H: Figure it out from there. They're circles. As the big one spins, the smaller ones move and collide, flip and wobble, knot and bust. Smaller circles form within that chaos creating even smaller circles and orbits. They create shapes like squares to triangles, to universes, curved flat from our outside perspective. Charge doesn't matter. We see the flat number line because two circles connect and spin in unison within larger ones within infinity.

Step I: Let me know if this sounds stupid.
