

To analyze what a number fundamentally is, I assumed it's $e^{i\theta}$.

It makes numbers between i -1 -i 1

I tried turning the numberline & e^{ix} spiral into infinite rotated circles and created spheres from them with interior i & $-i$. Turning them inside out etc. They layered. You go from $-i$ -1 i 1 aka -inside -1 +inside +1. And circle math was born from those infinite repeating layers getting broken down into infinity & dark dimensions like 3Dby3D. So $0 \rightarrow \infty \rightarrow 1 \rightarrow \infty \rightarrow 0$ loops.

Simply, fractals and lines are all rotations of circles, they're relative distortions. 1d is 0-1 split across infinity. The circle is analogous to a projection from a 0D projector, while we just see the screen at different angles. $2\pi=4\pi?=0=\infty$ ish That's the 1d I'm using as a foundation for my dimensions. A neutral circle, not a $1+$ -infinite numberline.

Here's my theoretical dimensional "protein folding" wave equation born of circle dimensions:

$$\Psi = e^{\text{Dimensions}}$$

$$\text{Simple} = e^{(P_n - 1)\theta}$$

$$\text{Better} = e^{(\phi^q)(P_n - 1)\theta}$$

Variables:

P_n =primes

θ =Numbers

ϕ =Golden ratio. Kickstarts motion via perfect near miss 0 spiral orbits 180° apart on a 1d neutral circle.

q =selects the side of 1: Classical vs quantum on a circle. If you do $\phi^0=1$, that's where light can sit with wave particle duality. -1 is fractions.

i is missing because it's 2D not 1D. Its hidden.

$$\text{Everything} \Psi = \Psi_1 * \Psi_2 \dots \Psi_{\infty}$$

You will have to use circles to calculate this, because infinities & orbits. Else you can't store variables at the shared 0 ∞ pole in higher dimensions or deal with irrationality I think.

The easy comprehensive example from our universe:

$$e^{(2d)*\text{interior}(3d)*\text{exterior}(3d)} \text{ or}$$

$$e^{i(j+k+y)(m+a+d)}$$

i=universe time direction + or -

j=angle

k=phase

y=shape like the triangle torus skeleton of electrons?

m=momentum vector

a=time angle

d=distance within the i time cone

Our universe has 2 time dimensions and 3 spatial dimensions split across the interior/exterior of particles & the universe itself. You can also view it as 3 dimensions per time charge so -3d & +3d. 3Dby3D' sections are practically interchangeable to 3D'by3D making duality.

Schrodinger's equation using my equation's terms - though I could be wrong:

$$e^{-(i/h)*H*t}$$

$$H=[\text{interior}(3d)*\text{exterior}(3d)]$$

t=(phase*time angle) which is redundant, possibly

i/h=h might be a variable from the higher multiverse like vacuum density thus why it's both negative & a fraction?

Okay so now we're gonna conceptualize these multiple dimensions.

0D The Infinite Nothingness

1D The Inversion Lens

Start with 0 through 1 then take infinite fractions or a half to lay in front, you now have an infinite real number line. $\infty/2$

Back to 0-1, if you rotate your perspective on it, the 0 & ∞ spots flip or the line becomes a circle with ∞ & 0 sharing a point. Both halves are infinite inverse copies. At the halfway point of the circle aka 1, it flips in on itself back towards 0 making this 1d universe highly unstable. Bye bye universe.

2D The Charge Flipper

As that 1D collapses, the energy clashes at 0 & spins into 2D or $+i -i$. It creates 2 loops with interiors $+i$ representing positive negative numbers. As a point goes around i into 0 or ∞ , the 0 causes it to flip charge to avoid collapse. That in turn creates our infinite $+/-$ number line when rotated into a $+/-$ number line. Two circular loops is its actual shape but they're sorta overlapping.

3D The Lightly Unstable Dark Particle/Universe

Here you can list the dimensions as $(x+y+z)$. This is an unstable dark universe. Doing a breakdown such as $2d*1d$ or $i*1d$ shows one axis is unstable. Torus particles here have to flip all xyz charges to affect time. Triangle is the most common shape for its rigidity but higher up orbits likely get more energetic. They exist in higher dimensions of primes or use the golden ratio spiral. Else the 1d loop collapses into the more stable 2d universes/particles. Creating a possible big bang in the process - Energy preservation after all. Small becomes big becomes small.

4D The Fabric of Spacetime?

4D or $2d*2d$. This is a flat universe with time or $i*2d$ or $-2d +2d$. It wraps around our universe's boundaries acting as the fabric I think. I'm still figuring this one out but the hyperbolic shape as it reaches 0 to infinity could shoot past 0 shape wise? When one charge approaches 0 the other technically does too & it cuts out the space around 0 & after. It might kinda roll into itself, cutting out the center, creating two time cones drifting apart. Interesting.

5D Another Dark Universe?

5d or $2d \times 3d$ is a dark universe that would get broken into $2d \times 2d \times 1d$ with 1d collapsing without fun orbits. Idk if dark matter pentagonal orbits exist in this one but to keep it from collapsing it'd probably need it

6D Its Like 3D

$6d = 3d \times 3d = 2d \times 2d \times 2d$ or $2d \times 4d$ allowing a 3d movie to play?

7D More Darkness

7D another dark universe that breaks into $1d \times 3d \times 3d$ or likely $5d \times 2d$. Idk if viewing it as 2 charged 5d or 5 charged 2d affects conceptualizing or works.

8D Home

8d is our universe. Gravity would be affecting 2/3 of the spatial dimensions which is why reversing gravity doesn't cause reverse time aka $+-$ or $-++$.

A black hole here could send you through 0 which is infinity, flipping every particle's time axis shooting you all across the anti time universe as background waves and new objects. It recycles itself by unwinding complex knots through the big bang 0∞ $+i$ time axis.

9D Stuff...

Ildr past this. That's why I assumed $(Prime_n - 1)$ for dimensions. Higher dimensions, bc $0 = \infty$, the shape eventually loops back. Primes wouldn't? I'd also assume the golden ratio is an example of the optimal prime number flipped 180° on the 1d becoming a fraction when its > 1 then back to prime when flipped again. It has to be absolutely irrational to infinitely avoid crashing into 0

For multiversal math, the multiverse has i time which acts as a giant gear turning our i gear & causing the higher multiverse layers and folds to move & recycle.

Here's a good ordering to visualize:

$$\begin{aligned}\text{Multiverse} &= e^{i(3d)}(\text{our Universe}) \\ 3d &= (\text{universe\#} + \text{membrane} + \text{vacuum density}) \\ \text{Universe} &= e^{i\{3d\}\{3d\}}\end{aligned}$$

This is assuming everything's the inside of everything so a universe could maybe be a particle. Why dimensions break up into almost quanta sections of stable dimensions.

Pure mad science speculation rambling from here. Feel free to skip & play around with the math yourself. Else enjoy this unscholarly articulation:

Particle & universe has duality & the inside = another's outside.

Dark matter comes from $0d \times 3d \times 3d$ or $3d \times 3d$ universe. Affecting all 3d variables of one of the 2 3d options yields time-like effects using (+++) to (---). Unlike binary symmetry using outside=inside, the dark matter exterior is simply its outside, & inside is a pocket dimension. Those pockets might be layered with other universes idk. Id also assume up to any prime # twists work for the torus though the golden ratio might be required to flex under extremely packed dark dimensions around $i0$. I haven't figured out how the torus twist relates to its movement.

The +- charge of time creates the electromagnetic force going from a positive interior positron out into a negative interior of a neg electron. An electron could even be a merely a photon linked with a 3 pointed (positive, negative, neutral) or a ($2d \times 1d$ looped) dark matter torus.

A proton would have fractions of the positive negative loops i phases, split from their j angle into $-1/3 - 1/3 + 2/3$ pairs or $1/2$ split = π radians. They can easily share 3 or 5 points on a dark matter torus here using the # symbol to represent neutral charge.

$-1/2 \#1/3 + 1/2 \#2/3$

$-1/2 \#2/5 + 1/2 \#3/5$

...

$-1/3 \#1/3 - 1/3 \#1/3 + 2/3 \#1/3$

$-1/3 \#1/5 + 1/3 \#1/5 - 1/3 \#1/5 + 1/3 \#2/5$

...

The $2/5$ instability in 5 pointed dark matter may result in shorter lifespan or more mass from our orientation? You can also have more loops & points. idk how unstable that'd become that's up to the golden ratio spiral or advanced structures.

There's probably heavier particles you can make with different fractions & torus.

Photons exist at the boundary of the $i - i$ cone making them move at c while dark matter creates drag on electrons giving mass via extra loops, indirect time stuff, & interior structure?

All this may form layers of particles within particles within universes to multiverses back to inside particles. The outside of a +particle can be inside of a -universe whose outside is a +universe interior or point on a dark matter torus particle universe... I think

Stuff loops from infinity to 0 bc it's identical. What looks like a line or fractals becomes circles when rotated & folded in higher dimensions. Maybe this can help solve quantum computers with 0 orbiting prime spirals of the dark matter torus around the i axis, nuclear fusion idk, whatever. I'm bad at normal math so I folded the numberline into itself to get to this concept.
