

Looking at my previous equation about the universe being a circle, I wanted to add a possible testable utility of it. So here's a simple way to test its analog calculation ability by converting addition, subtract and multiplication into physical variables on a blank vinyl. This is untested.

My main wave equation = $e^{(\varphi^q)(P_n-1)\theta}$

Variables:

P_n =primes

φ =Golden ratio. Kickstarts motion via perfect near miss 0 spiral orbits 180° apart on a 1d neutral circle.

q =which side of 1: Classical vs quantum on a circle

θ =Numbers

Here's the Calculator version using a normal record player. I think I wrote it right?

Needle's θ or Output = $e^{(\varphi^1)(P_n-1)N(x)}$

$N(x) = \varphi^x(CR \cdot T)$

$P_n-1=1$

$C=0$'s circle or radius%

R =Vinyls radius

X =inputA or Needle's Radius

T =InputB or RPM

To convert inputs to variables:

InputA or $X = \varphi^x(CR)$

InputB or $T = B \cdot \text{RPM}$

Output=radians. Flat is 0 and from there its $0-2\pi$?

The physical math:

By changing rpm or moving away, the drag on the needle produces and output or angle.

By increasing the rpm, the centrifugal force should shoots the needle forward till it reaches equilibrium. The drag of the disk produces the angle for your output as multiplication.

By moving just the radius, you're performing addition slowly affecting the needle's drag angle.

Primes increase complexity types I think. This is all new to me.

To mark the vinyl aka set -1 0 1 2 3...

Draw circles at

$f(x) = \varphi^x(CR)$ Using the variables from before.
